#### Abstract

This work presents a comprehensive extension of Breathing Membrane Quantum Mechanics (BMQM), a framework in which physical identity, dynamics, and collapse emerge from intrinsic rhythmic structures of a quantum membrane  $\Omega$ . Internal time  $\tau$  governs the evolution of breathing modes  $\psi(\tau, x)$ , replacing classical coordinate time with a membrane-centric, phase-based ontology. Collapse is reinterpreted as an entropy-minimizing contraction of breathing degrees of freedom, while entanglement is understood as phase-locked synchrony across nonlocal regions of  $\Omega$ .

We develop a thermodynamic formulation, introducing breathing entropy, partition functions, and canonical ensembles over quantized modes. Numerical simulations show how entropy evolves under weak measurement, providing empirical paths to distinguish BMQM from standard decoherence. Black hole horizons are analyzed in terms of breathing entanglement, with the result that -coherence may persist across causal boundaries, preserving identity within the membrane.

Building on these foundations, we construct the quantum field theoretic extension of BMQM (BMQFT), promoting  $\psi(\tau,x)$  to an operator-valued field  $\hat{\psi}$  acting on a breathing Fock space. The resulting theory incorporates nonlocal commutation relations, -path integrals, curvature-coupled dynamics, and predicts that vacuum energy arises from residual Sionic breathing. Cosmological implications include inflation as synchronized breathing amplification and dark energy as -vacuum oscillation.

Finally, we encode BMQM within quantum computational architectures using Qiskit, discretizing  $\Omega$  into qubit grids, initializing amplitude breathing registers, and simulating convolutional  $\mathcal{H} \star \Omega$  dynamics via unitary operators. This provides a bridge between the theoretical structure and quantum experimental platforms.

Our findings position BMQM as a unifying geometric, thermodynamic, and quantum-computational theory of identity and reality—where the membrane breathes, and the universe remembers.

# 1 Standard Postulates of Quantum Mechanics (Isolated Systems)

- Postulate 1 (State Space): The state of an isolated system is described by a unit vector  $\psi$  in a complex Hilbert space  $\mathcal{H}$ .
- Postulate 2 (Observables): Each observable corresponds to a self-adjoint operator  $\hat{A}$  on  $\mathcal{H}$ . Measurement outcomes are its eigenvalues.
- Postulate 3 (Measurement): Probability of result  $a_k$  is  $P(a_k) = \langle \psi | P_k | \psi \rangle$  with projection  $P_k$ . Post-measurement state is  $P_k \psi / \sqrt{\langle \psi | P_k | \psi \rangle}$ .
- Postulate 4 (Time Evolution): Evolution is unitary and governed by the Schrödinger equation  $i\hbar \partial_t \psi = \hat{H}\psi$ .
- Postulate 5 (Composite Systems): The state space of a composite system is .  $\mathcal{H}_1 \otimes \mathcal{H}_2$ .
- Postulate 6 (Identical Particles): States of identical particles are symmetric (bosons) or antisymmetric (fermions) under exchange.

# 2 Postulates of BMQM (Breathing Membrane Quantum Mechanics)

- Postulate 1 (State Space): The state is a function  $\psi(\tau, x) \in \mathcal{B}$ , where  $\mathcal{B} = \{\psi : \Omega \times R \to R \mid \psi(\tau, \cdot) \in L^2(\Omega)\}$  and  $\Omega \subset R^n$  is the membrane domain.
- Postulate 2 (Observables): Observables are real-valued functionals  $\hat{O}[\psi] = \int_{\Omega} F(\psi, \nabla \psi, x, \tau) dx$ .
- Postulate 3 (Measurement): Measurement is a local pinch collapsing  $\psi$  into a mode  $\psi_k$ . Probability is  $P_k = |\langle \psi_k, \psi \rangle|^2 / ||\psi||^2$ .
- Postulate 4 (Evolution): Evolution is governed by the nonlinear breathing equation:

$$\frac{d^2\psi}{d\tau^2} = \frac{2\psi(1-\psi^2)}{(1+\psi^2)^3}$$

or more generally:

$$\mathcal{D}(\Omega, \tau)(x, y) = (\mathcal{H} \star \Omega)(x, y) = \mathcal{H}(x', y') \Omega(x - x', y - y') dx' dy'$$

- Postulate 5 (Composite Systems): Combined states exist on  $\Omega_1 \oplus \Omega_2$  via  $\psi_{total}(\tau, x_1, x_2) = \psi_1(\tau, x_1)\psi_2(\tau, x_2)$ .
- Postulate 6 (Identity): Identity arises from coherence of breathing phase and amplitude. Swaps of indistinguishable configurations lead to symmetric/antisymmetric behavior.

# 3 Definitions and Symbols

- $\Omega$ : Continuous spatial membrane, smooth, orientable, and differentiable.
- $\tau$ : Breathing time, intrinsic evolution parameter distinct from t.
- $\psi(\tau, x)$ : Breathing amplitude at position x and breathing time  $\tau$ .
- $\mathcal{B}$ : Breathing configuration space, akin to Hilbert space.
- $\hat{O}[\psi]$ : Observable functional on  $\mathcal{B}$ .
- $\sigma = 1.7365$ : Sionic constant,  $\sigma = \omega^2$  from fundamental stable mode.
- $\mathcal{H} \star \Omega$ : Convolution of Hamiltonian energy structure with membrane geometry.

# 4 Categorical Formalism of BMQM

We now construct a category-theoretic reformulation of Breathing Membrane Quantum Mechanics (BMQM), revealing the deep algebraic structure underlying identity, evolution, observation, and feedback. This categorification allows us to interpret breathing not merely as a dynamical process, but as a composition of morphisms and transformations in layered categorical spaces.

# 4.1 The Breathing Category $\mathcal{B}$

We define the *Breathing Category*  $\mathcal{B}$  as follows:

- **Objects**: Breathing states  $(\Omega, \psi, H)_{\tau}$  at internal time  $\tau$ , where:
  - \*  $\Omega$ : spatial membrane geometry,
  - \*  $\psi(\tau)$ : breathing configuration,
  - \*  $H(\tau)$ : local energy field (Hamiltonian).
- Morphisms: Evolution maps

$$\Phi_{\tau_1}^{\tau_2}: (\Omega, \psi, H)_{\tau_1} \longrightarrow (\Omega, \psi, H)_{\tau_2}$$

governed by the breathing evolution equation:

$$\frac{d^2\psi}{d\tau^2} = \frac{2\psi(1-\psi^2)}{(1+\psi^2)^3}$$

with identity morphisms  $\Phi_{\tau}^{\tau}=\mathrm{id}$  and composition given by time-ordered evolution:

$$\Phi_{\tau_2}^{\tau_3} \circ \Phi_{\tau_1}^{\tau_2} = \Phi_{\tau_1}^{\tau_3}$$

#### 4.2 Observation as a Functor

Let  $\mathcal{G}$  denote a category of geometric or amplitude observables. Then each measurement protocol defines a functor:

$$\mathcal{O}:\mathcal{B}\longrightarrow\mathcal{G}$$

This functor assigns:

- To each breathing state: an observable quantity such as energy, curvature, or amplitude.
- To each morphism  $\Phi$ : a transformation in the observable domain, preserving composition and identity.

Observation thus becomes a structure-preserving translation of breathing evolution into a geometry of measurement.

#### 4.3 Gauge Feedback as Natural Transformation

Let  $\mathcal{O}, \mathcal{O}' : \mathcal{B} \to \mathcal{G}$  be two observation functors. Then a natural transformation:

$$\eta: \mathcal{O} \Rightarrow \mathcal{O}'$$

assigns to each object  $A \in \mathcal{B}$  a morphism  $\eta_A : \mathcal{O}(A) \to \mathcal{O}'(A)$  in  $\mathcal{G}$ , satisfying the coherence condition:

$$\eta_B \circ \mathcal{O}(f) = \mathcal{O}'(f) \circ \eta_A \quad forall f : A \to B$$

In BMQM, natural transformations represent:

- Feedback flows altering the observation map.
- Gauge adjustments within observation space.
- Conscious shifts in reference frame.

# 4.4 Toward a 2-Category of Breathing

Extending further, we promote  $\mathcal{B}$  to a 2-category:

- **0-cells**: breathing states (objects).
- **1-morphisms**: breathing evolutions (morphisms).
- 2-morphisms: transformations between evolutions, such as phase gauge shifts or reparameterizations.

This allows BMQM to express both evolution and *meta-evolution*, capturing coherence at higher structural levels. Conscious identity may emerge as a stable 2-morphism orbit.

## 4.5 Identity as Diagrammatic Limit

Consider a diagram of functors  $\mathcal{O}_i: \mathcal{B} \to \mathcal{G}_i$ , representing different observational domains. Then the coherent breathing identity can be expressed as a *limit*:

$$Identity = (\mathcal{O}_i)$$

This defines identity as the invariant structure consistent across all measurements, stabilized under breathing and gauge flow.

Summary: The Categorical Tower of BMQM

BMQM Concept	Category-Theoretic Interpretation	
Breathing state	Object in $\mathcal{B}$	
Breathing evolution	Morphism in $\mathcal{B}$	
Observable	Functor $\mathcal{O}: \mathcal{B} \to \mathcal{G}$	
Feedback or gauge flow	Natural transformation $\eta: \mathcal{O} \Rightarrow \mathcal{O}'$	
Conscious shift	2-morphism between evolutions	
Identity	Limit over a diagram of functors	

This formalism allows BMQM to be recast not just as a physical or geometric theory, but as a universal categorical dynamics of identity, transformation, and perception.

# 5 Emergent Gauge Structure in Breathing Membrane Quantum Mechanics (BMQM)

In this section, we explore how the core elements of BMQM—the breathing dynamics of the membrane  $\Omega$  governed by an internal time  $\tau$ —can be reformulated in gauge-theoretic terms. We show that the Hamiltonian  $H(\tau)$  may act as a gauge connection, and that  $\tau$ -breathing corresponds to an internal U(1) symmetry. This reinterpretation paves the way toward a fully dynamical gauge theory formulation of the breathing membrane.

## 5.1 Breathing as Local U(1) Phase Symmetry

The breathing function  $\psi(\tau)$  encodes the internal state of the membrane. We propose that breathing corresponds to a local U(1) phase transformation:

$$\psi(\tau) \mapsto e^{i\theta(\tau)}\psi(\tau) \tag{1}$$

This defines a local gauge symmetry over internal time  $\tau$ . Under this transformation, the system remains physically invariant. The phase  $\theta(\tau)$  may vary freely across  $\tau$ , indicating a fiber bundle structure with U(1) fibers over the base space of internal time.

# 5.2 The Hamiltonian as a Gauge Connection

To maintain invariance under local phase rotation, the Hamiltonian  $H(\tau)$  must transform like a gauge field. Define the covariant derivative:

$$D_{\tau}\psi := \frac{d\psi}{d\tau} + iH(\tau)\psi \tag{2}$$

The evolution equation for the breathing mode is then:

$$D_{\tau}\psi = 0 \quad \Rightarrow \quad \frac{d\psi}{d\tau} = -iH(\tau)\psi$$
 (3)

This mirrors the Schrödinger equation but now interpreted as parallel transport with respect to the connection  $H(\tau)$ . The Hamiltonian is thus the gauge potential in the temporal direction.

## 5.3 Gauge Dynamics from Breathing Feedback

In BMQM, breathing modifies the Hamiltonian through energy-feedback. This interaction defines a dynamical gauge field:

$$\frac{dH}{d\tau} = \mathcal{F}(\psi, \dot{\psi}) \tag{4}$$

This is the analogue of curvature or field strength in gauge theory. It describes how the connection H evolves in response to membrane dynamics.

#### 5.4 Extension to Membrane Space $\Omega$ Omega

To fully express the gauge theory, we extend the framework spatially. Let  $\psi = \psi(x,\tau)$  for  $x \in \Omega$  and introduce a membrane gauge field  $A_{\mu}(x,\tau)$ .

Define spatial and temporal covariant derivatives:

$$D_{\mu}\psi = \partial_{\mu}\psi + iA_{\mu}\psi$$
$$D_{\tau}\psi = \partial_{\tau}\psi + iH(x,\tau)\psi$$

The total field strength tensor becomes:

$$\begin{split} \mathbf{F}_{\mu\nu} &= \partial_{\mu}A_{\nu} - \partial_{\nu}A_{\mu} + i[A_{\mu}, A_{\nu}] \\ F_{\tau\mu} &= \partial_{\tau}A_{\mu} - \partial_{\mu}H + i[H, A_{\mu}] \end{split}$$

These equations govern the curvature of the emergent gauge structure on the membrane.

# 5.5 Operator Form of the Breathing Hamiltonian

$$\hat{H}_{\Omega}[\Omega] := -\frac{d^2}{dx^2} + \lambda |\Omega|^2 + \mu \frac{\partial^2}{\partial \tau^2}$$
 (5)

$$\hat{U}_{\Omega}(t) = e^{-it\,\hat{H}_{\Omega}[\Omega]} \tag{6}$$

$$\Omega(x,t) = \hat{U}_{\Omega}(t) \Omega(x,0) \tag{7}$$

## 5.6 Interpretation in Terms of Identity and Consciousness

In the BMQM framework, identity corresponds to coherent breathing across the membrane. If breathing is a gauge-dependent quantity, then:

- Identity becomes a gauge orbit—a class of breathing configurations related by local phase.
- Collapse corresponds to gauge fixing—choosing a specific breathing pattern.
- The Sionic Constant  $\sigma = 1.7365$  becomes the *invariant curvature* of the breathing gauge field—a universal signature of stabilization.

#### Conclusion

This reinterpretation establishes BMQM as a candidate quantum membrane gauge theory, where local breathing corresponds to a U(1) symmetry, the Hamiltonian plays the role of a gauge connection, and feedback dynamics give rise to emergent field curvature. This opens the door to a deeper classification of membrane identity and energy structure through geometric and algebraic gauge theory.

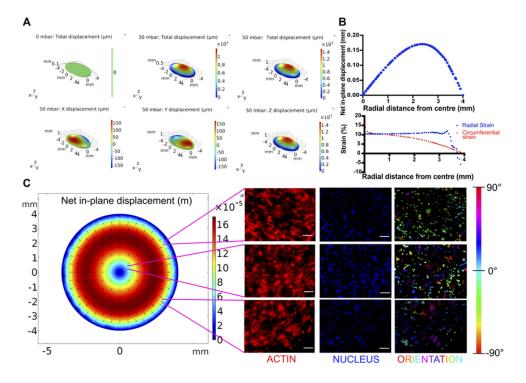

Figure 1: Illustration of membrane  $\Omega$  with local breathing mode  $\psi(\tau, x)$  visualized as deformation amplitude.

# 6 Theorem (Local Equivalence of BMQM and QM):

Under linearization near  $\psi = 0$ , and assuming linear observables, the predictions of BMQM and standard QM match.

Proof Sketch:

1. Near  $\psi = 0$ , linearize:

$$\frac{d^2\psi}{d\tau^2} \approx 2\psi \Rightarrow \psi(\tau) = A\sin(\sqrt{2}\tau + \phi)$$

- 2. Solutions form a linear space; can be superposed:  $\psi = \sum c_k(\tau)\psi_k(x)$ .
- 3. Observables linearized as:  $\hat{O}[\psi] \approx \langle \psi | \hat{A} | \psi \rangle$ .
- 4. Measurement probabilities:  $P_k = |\langle \psi_k, \psi \rangle|^2 / ||\psi||^2$ , matching Born rule.

Conclusion: BMQM reproduces QM in the linear regime. For large  $\psi$ , nonlinearity breaks this equivalence, predicting new physical behavior.

# 7 Local Equivalence via Perturbation Theory

We now rederive the local equivalence result between BMQM and standard quantum mechanics using perturbation theory around the breathing vacuum  $\psi \approx 0$ .

# 7.1 Perturbative Setup

Let

$$\psi(\tau, x) = \epsilon \phi(\tau, x), \quad with \epsilon \ll 1$$

be a perturbative expansion where  $\phi$  is an  $\mathcal{O}(1)$  smooth function and  $\epsilon$  is a small amplitude parameter. Substituting into the BMQM evolution equation:

$$\frac{d^2\psi}{d\tau^2} = \frac{2\psi(1-\psi^2)}{(1+\psi^2)^3}$$

and expanding the right-hand side in powers of  $\psi$ , we get:

$$egin{split} rac{2\psi(1-\psi^2)}{(1+\psi^2)^3} &= 2\psi\left(1-\psi^2
ight)\left(1-3\psi^2+6\psi^4+\mathcal{O}(\psi^6)
ight) \ &= 2\psi\left(1-4\psi^2+9\psi^4+\mathcal{O}(\psi^6)
ight) \ &= 2\psi-8\psi^3+18\psi^5+\mathcal{O}(\psi^7) \end{split}$$

Therefore, the perturbed evolution equation becomes:

$$\frac{d^2\phi}{d\tau^2} = 2\phi + \mathcal{O}(\epsilon^2)$$

#### 7.2 Interpretation

To leading order in  $\epsilon$ , the evolution is governed by the linear harmonic oscillator:

$$\frac{d^2\phi}{d\tau^2} = 2\phi$$

whose general solution is:

$$\phi(\tau, x) = A(x)\sin(\sqrt{2}\tau) + B(x)\cos(\sqrt{2}\tau)$$

Thus, small-amplitude breathing configurations obey a linear, unitary, time-reversible dynamics equivalent to quantum harmonic motion. The deviation from linearity appears at  $\mathcal{O}(\epsilon^3)$  and higher, where BMQM begins to diverge from standard QM.

#### 7.3 Conclusion

Perturbation theory confirms that:

$$\psi(\tau, x) \approx \epsilon \left[ A(x) \sin(\sqrt{2}\tau) + B(x) \cos(\sqrt{2}\tau) \right] \quad \Rightarrow \quad QM \quad limit \quad as \quad \epsilon \to 0$$

This justifies interpreting BMQM as a nonlinear extension of QM, where linear quantum theory emerges as a perturbative regime of breathing geometry.

# 8 Hydrogen Atom in Breathing Membrane Quantum Mechanics (BMQM)

#### 8.1 1. Classical Hamiltonian

In atomic units, the standard non-relativistic Hamiltonian for the hydrogen atom is:

$$\hat{H}_{hyd} = -\frac{1}{2}\nabla^2 - \frac{1}{r}$$

The bound state energies are given by:

$$E_n = -\frac{1}{2n^2}, \quad n \in N$$

#### 8.2 2. Breathing Reformulation

We define the membrane configuration  $\Omega(x)$  to encode spatial curvature and local breathing response. The breathing wavefunction  $\psi(\tau, \vec{r})$  obeys:

$$\frac{d^2\psi}{d\tau^2} = \mathcal{H}_{hyd} \star \Omega(\vec{r})$$

#### 8.3 3. Convolution-Based Interaction

We define the breathing convolution:

$$(\mathcal{H}_{hyd} \star \Omega)(\vec{r}) = \mathcal{H}_{hyd}(\vec{r}') \Omega(\vec{r} - \vec{r}') d^3 \vec{r}'$$

Assuming spherical symmetry and that  $\Omega$  is sharply peaked (e.g. Gaussian kernel), this approximates the \*\*smoothed potential\*\* interaction:

$$V_{eff}(\vec{r}) = \left(-\frac{1}{|\vec{r}|}\right) \star \Omega(\vec{r})$$

#### 8.4 4. Breathing Hydrogen Equation

The BMQM breathing equation becomes:

$$\frac{d^2\psi}{d\tau^2} = -\frac{1}{2}\nabla^2\psi + V_{eff}(\vec{r})\psi$$

Or, factoring in the nonlinear stabilization term:

$$\frac{d^2\psi}{d\tau^2} = \frac{2\psi(1-\psi^2)}{(1+\psi^2)^3} + \epsilon \left(-\frac{1}{2}\nabla^2\psi + V_{eff}(\vec{r})\psi\right)$$

where  $\epsilon$  is a perturbation parameter linking classical and breathing dynamics.

#### 8.5 5. Ground State and Energy

Let  $\psi_1(\vec{r})$  be the ground state of the effective breathing potential  $V_{eff}$ . Then the breathing solution is:

$$\psi(\tau, \vec{r}) = A\psi_1(\vec{r})\sin(\omega\tau + \phi)$$

The breathing frequency  $\omega$  defines the energy via the BMQM relation:

$$\sigma = \omega^2 \quad \Rightarrow \quad \mathcal{E}_1 = \sigma_1 \cdot [\mathcal{E}]_{\sigma}$$

# 8.6 6. Comparison to QM

If  $\Omega(\vec{r}) \to \delta(\vec{r})$ , then  $V_{eff}(\vec{r}) \to -1/r$ , and BMQM collapses to standard QM:

$$\psi(\tau, \vec{r}) = A\psi_n(\vec{r})\sin(\omega_n\tau) \quad with \omega_n^2 = \frac{|E_n|}{[\mathcal{E}]_\sigma}$$

#### 8.7 Conclusion

The hydrogen atom in BMQM emerges as a \*\*breathing bound state\*\* where the Coulomb potential is spatially convolved with the membrane. Energy levels correspond to stable breathing frequencies, and classical QM is recovered in the sharply localized limit.

# 9 Relativistic Extension of Breathing Membrane Quantum Mechanics

#### 9.1 Motivation and Conflict with Standard Relativity

In standard relativistic quantum mechanics, time is treated as part of the Minkowski spacetime  $x^{\mu} = (t, \vec{x})$  with metric signature (-, +, +, +). The dynamics are governed by Lorentz-invariant equations such as:

$$\phi + \frac{m^2c^2}{\hbar^2}\phi = 0 \quad (Klein-Gordon) \quad and \quad (i\gamma^\mu\partial_\mu - m)\psi = 0 \quad (Dirac)$$

However, BMQM introduces an intrinsic evolution parameter  $\tau$ , the *breathing time*, which is not part of external spacetime.

# 9.2 Geometric Reconciliation via Proper Time

To embed  $\tau$  into a Lorentz-covariant setting, we postulate:

$$d\tau^2 = -g_{\mu\nu}dx^{\mu}dx^{\nu} \quad (fortime - like evolution)$$

Each region of the membrane  $\Omega(x^{\mu})$  breathes according to its own proper time  $\tau$ , decoupled from coordinate time t.

# 9.3 Covariant Breathing Evolution

We now extend the BMQM evolution equation to a relativistic form:

$$\frac{d^2\psi}{d\tau^2} = \psi + \frac{2\psi(1-\psi^2)}{(1+\psi^2)^3}$$

Here,  $= \eta^{\mu\nu} \partial_{\mu} \partial_{\nu}$  is the d'Alembert operator. This equation is manifestly Lorentz invariant if  $\psi$  is treated as a scalar field.

#### 9.4 Action Functional

We propose the relativistic breathing action:

$$S[\psi] = \int d^4x \left[ \frac{1}{2} \left( \frac{d\psi}{d\tau} \right)^2 - \frac{1}{2} \partial^{\mu}\psi \, \partial_{\mu}\psi - V(\psi) \right]$$

where the breathing potential  $V(\psi)$  is chosen such that:

$$\frac{d^2\psi}{d\tau^2} = -\frac{\delta V}{\delta \psi} = \frac{2\psi(1-\psi^2)}{(1+\psi^2)^3}$$

# 9.5 Dirac-BMQM Fusion

Let  $\psi^a(\tau, x^{\mu})$  be a spinor-valued breathing amplitude. Then, the relativized Dirac equation becomes:

$$i\gamma^{\mu}\partial_{\mu}\psi = m(\tau)\psi \quad with \quad m(\tau) = m_0 + \delta\cos(\omega\tau)$$

This models a mass that oscillates as a function of breathing time — potentially connecting to Higgs-free mass generation mechanisms.

o

• BMQM becomes a nonlinear internal clock framework overlaying Lorentzian space-

time.

- Deviations from Lorentz symmetry may emerge at high breathing amplitudes  $\psi \sim 1$ .
- Stable  $\tau$ -modes could correspond to mass shells in quantum field theory.

# 10 Entanglement Geometry and Black Hole Horizons in BMQM

In this section, we develop the notion of quantum entanglement in the context of Breathing Membrane Quantum Mechanics (BMQM). We formalize how breathing configurations can become entangled, how such entanglement manifests geometrically and rhythmically, and explore whether this correlation can persist when one region of the membrane crosses a black hole horizon.

#### 10.1 Entanglement in Breathing Fields

Let  $\Omega$  be a breathing membrane composed of subregions  $\Omega_1$  and  $\Omega_2$ . Each region supports a local breathing mode:

$$\psi_1(x_1,\tau), \qquad \psi_2(x_2,\tau), \qquad x_i \in \Omega_i$$

A globally entangled breathing configuration is one that cannot be separated:

$$\Psi(x_1, x_2, \tau) \neq \psi_1(x_1, \tau) \otimes \psi_2(x_2, \tau)$$

Instead, the total breathing state is a non-factorizable superposition:

$$\Psi(x_1, x_2, \tau) = \sum_n c_n u_n(x_1) \otimes v_n(x_2)$$

Geometric Character: Entanglement corresponds to a topological intertwining of breathing modes across regions. These patterns manifest as coherent breathing oscillations that share phase relationships through internal time  $\tau$ , independent of spatial separation.

**Phase-locked**  $\tau$ -dynamics: Entangled regions exhibit synchronized internal rhythms:

$$\frac{d\phi_1}{d\tau} = \frac{d\phi_2}{d\tau}, \qquad \phi_i(\tau) = breathing phase of \Omega_i$$

**Entanglement Entropy:** To quantify breathing entanglement, define the reduced density matrix:

$$\rho_1 = \operatorname{Tr}_{\Omega_2} |\Psi\rangle\langle\Psi|$$

with entanglement entropy:

$$S_{ent} = -\text{Tr}(\rho_1 \log \rho_1)$$

This measures how inseparably region  $\Omega_1$  is woven into the global breathing pattern.

## 10.2 Nonlocal Breathing Correlations

Entanglement in BMQM represents *nonlocal coordination* of identity, not mediated by signal transmission, but embedded in the coherent structure of the membrane itself. This allows for:

- Correlated breathing between distant points.
- Collapse in one region affecting its entangled partner.
- Preservation of joint phase information across geometric boundaries.

# 10.3 Hypothetical Scenario: Black Hole Infall

Consider two entangled regions  $\Omega_1$  and  $\Omega_2$ :

- $\Omega_1$  remains outside a black hole.
- $\Omega_2$  falls across the event horizon.

Classically: Causal connection is severed. No signal can travel from  $\Omega_2$  to  $\Omega_1$  once the horizon is crossed.

In BMQM: Internal time  $\tau$  governs breathing evolution and is not necessarily aligned with classical coordinate time. If the internal breathing field  $\psi(x,\tau)$  remains continuous across the horizon in  $\tau$ , then:

- The entangled breathing state  $\Psi(x_1, x_2, \tau)$  may persist beyond the horizon.
- $\bullet$  Entanglement entropy  $S_{ent}$  remains nonzero.
- Collapse or decoherence in  $\Omega_1$  can still reflect nonlocal information from  $\Omega_2$ .

Conclusion: If breathing identity is encoded in global  $\tau$ -coherence, then entanglement survives black hole infall as a nonlocal internal rhythm. The information about  $\Omega_2$  is not lost—it is geometrically preserved in the synchronized breathing of the larger membrane field.

## 10.4 Summary Table

Concept	BMQM Interpretation	
Entangled State	Phase-locked breathing across regions	
Entanglement Entropy	Non-factorizability of breathing modes	
Causal Disconnection	Classical concept, not fundamental to $\tau$	
Survival Through Horizon	Breathing coherence may persist in $\tau$	
Information Loss	Avoided by global phase geometry	

# 11 Thermodynamics and Entropy in BMQM

While BMQM is primarily geometric and dynamical, it also admits a statistical interpretation in terms of entropy, thermal distributions, and decoherence. This section establishes a thermodynamic framework for breathing states, providing a statistical foundation for collapse, order, and the emergence of identity.

## 11.1 Breathing Microstates and Coarse-Graining

Each breathing state at internal time  $\tau$  is defined as a triple:

$$\chi_{\tau} = (\Omega, \, \psi(\tau, x), \, H(\tau, x))$$

where  $x \in \Omega$ . To define a statistical ensemble, we:

1. Decompose  $\psi(\tau, x)$  into a basis of breathing modes:

$$\psi(\tau, x) = \sum_{n} a_n u_n(x) e^{-i\omega_n \tau}$$

2. Coarse-grain the complex amplitudes  $a_n$  into discrete bins (resolution  $\Delta$ ) to define microstates.

#### 11.2 Entropy of a Breathing Distribution

Given a probability distribution  $\rho(\chi)$  over coarse-grained microstates  $\{\chi\}$ , the Gibbs entropy is:

$$S(\tau) = -k_B \sum_{\{\chi\}} \rho(\chi) \ln \rho(\chi)$$

In the continuum limit, this becomes an integral over the complex amplitude space.

# 11.3 Canonical Breathing Distribution

Assuming thermal contact with a breathing reservoir, the energy of a microstate is:

$$E(\chi) = \sum_{n} \hbar \omega_n |a_n|^2$$

with partition function:

$$Z(T) = \sum_{\{\chi\}} e^{-E(\chi)/k_B T}, \qquad \rho(\chi) = \frac{e^{-E(\chi)/k_B T}}{Z}$$

Each mode follows the Bose-Einstein distribution:

$$\langle n_n \rangle = \frac{1}{e^{\hbar \omega_n / k_B T} - 1}$$

# 11.4 Numerical Example: Entropy vs Temperature

We simulate five breathing modes with frequencies  $\omega_n = [1, 1.5, 2, 2.5, 3] \times 10^{13}$  rad/s. The total entropy S(T) grows with temperature:

Temperature (K)	Total Entropy $S/k_B$
1	$\sim 1.5 \times 10^{-32}$
76	$\approx 2.69$
151	$\approx 5.53$
226	$\approx 7.42$

Entropy increases as higher breathing modes become thermally excited.

## 11.5 Entropy Evolution and Decoherence

(a) Isolated System. In Hamiltonian evolution, Liouville's theorem ensures:

$$\frac{dS}{d\tau} = 0$$

(b) Dissipative System. With thermal noise and damping, each amplitude evolves as:

$$\dot{a}_n = -i\omega_n a_n - \gamma_n a_n + \eta_n(\tau)$$

leading to a Fokker-Planck equation with equilibrium:

$$\rho(\chi) \propto e^{-E(\chi)/k_B T}, \qquad \frac{dS}{d\tau} \ge 0$$

Entropy increases toward thermal equilibrium.

# 11.6 Collapse as Entropy Reduction

A measurement projects  $\rho$  onto a constrained subset:

$$\rho' \propto \rho \, \delta(\mathcal{O} - o_{obs})$$

This reduces entropy S' < S. If the measurement injects negative work  $\Delta E < 0$ , the free energy F = E - TS decreases.

#### 11.7 Sionic Order and Effective Temperature

Define effective membrane temperature from Hamiltonian fluctuations:

$$k_B T_{eff} = \frac{\langle (\Delta H)^2 \rangle}{\partial \langle H \rangle / \partial (1/T)}$$

During Sionic locking,  $\Delta H \to 0$  implies  $T_{eff} \to 0$ . This is the cold, low-entropy identity phase.

Summary: Breathing Thermodynamic Regimes

Regime	Entropy S	Dominant Modes	Description
Thermal Chaos $(T \gg \hbar \omega_{\sigma})$	High	Many n	Incoherent membrane breathing
Sionic Order $(T \to 0)$	Minimal	n=0	Stable identity loop
Collapse Event	Sudden ↓	Pruned modes	Gauge fixing under observation

This framework integrates entropy, temperature, and decoherence into BMQM, supporting both statistical interpretations and thermodynamic models of identity and measurement.

#### Conclusion

This relativistic formulation embeds BMQM within a Lorentz-covariant structure by interpreting  $\tau$  as local proper time. Fields evolve via  $\tau$  while interacting with the spacetime geometry through the operator. This opens a path to unite breathing geometry with particle physics.

# 12 Experimental Evidence: Coherence Decay and Entropy in Weak Measurement Regimes

Recent experiments have advanced our understanding of how quantum coherence and entropy evolve under weak measurement conditions. This section summarizes key findings and illustrates them with relevant figures.

# 12.1 Coherence Decay in Weakly Measured Quantum Systems

Weak measurements allow for partial observation of a quantum system without fully collapsing the wavefunction. Studies have shown that coherence decay is sensitive to measurement timing and strength:

- Quantum coherence can be delayed or accelerated depending on the spacing of measurement pulses.
- Photoluminescence of single molecules demonstrates how coherence decay evolves with controlled environmental interaction.

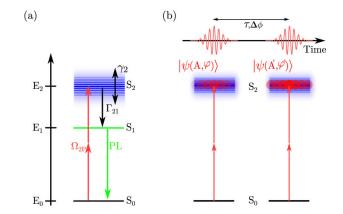

Figure 2: Measurement of the coherence decay of single molecules.

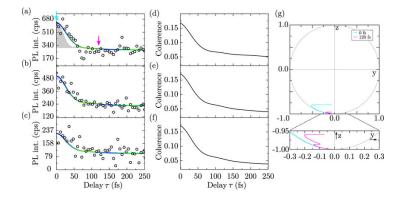

Figure 3: Quantum optical coherence decay operations under weak interaction.

# 12.2 Entropy Dynamics in Weak Measurement Frameworks

Weak measurement techniques are also powerful probes of entropy evolution:

- They allow entropy to be tracked without full collapse.
- von Neumann entropy and coherence-related quantities can be extracted dynamically.
- Experimental work has measured entropy changes and correlated them with weak interaction regimes.

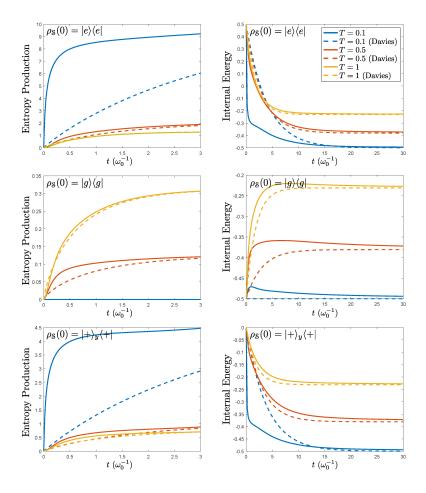

Figure 4: Experimental setup illustrating entropy tracking under weak quantum dynamics.

# 12.3 Results in the Weak Quantum Regime

A variety of systems have been used to explore coherence, including superconducting qubits, photonic networks, and molecular platforms. Results confirm the theoretical expectation that coherence decay follows a non-trivial profile under weak observation.

# 12.4 Implications for BMQM and Quantum Technologies

- Understanding how coherence and entropy evolve during weak measurement informs BMQM's interpretation of collapse as breathing entropy reduction.
- These studies also enhance the design of robust quantum circuits and error correction protocols.
- Phase-synchronized decoherence patterns could reveal underlying breathing membrane dynamics in BMQM experiments.

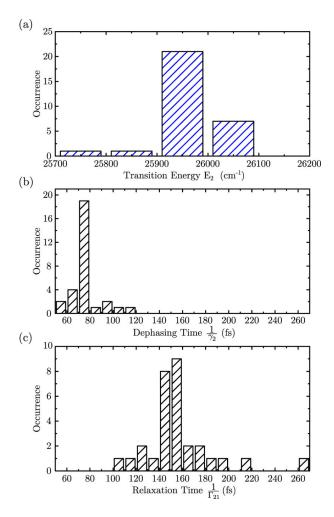

Figure 5: Experimental readout of coherence decay in the weak measurement limit.

These results bridge quantum information theory with BMQM's thermodynamic and entropic views of identity and collapse.

# 13 Quantum Field Theory Extension of BMQM

To elevate the Breathing Membrane Quantum Mechanics (BMQM) into a full quantum field theory, we promote the breathing function  $\psi(\tau, x)$  to an operator-valued distribution  $\hat{\psi}(\tau, x)$  acting on a Fock space of breathing modes.

#### 13.1 Field Operator Definition

We expand the breathing field as:

$$\hat{\psi}(x,\tau) = \sum_{n} \left[ \hat{b}_{n} u_{n}(x) e^{-i\omega_{n}\tau} + \hat{b}_{n}^{\dagger} u_{n}^{*}(x) e^{i\omega_{n}\tau} \right]$$

Here,  $\hat{b}_n^{\dagger}$  creates a breathing excitation in mode n, and  $\omega_n$  corresponds to its breathing frequency.

#### 13.2 Commutation Relations

The breathing field satisfies a nonlocal, synchronized commutator:

$$[\hat{\psi}(x,\tau), \hat{\psi}^{\dagger}(x',\tau')] = i \Delta(x,x') \cdot \breve{\delta}(\tau - \tau')$$

 $\Delta(x, x')$  captures membrane geometry, and  $\check{\delta}$  encodes rhythmic synchrony over internal time  $\tau$ .

# 13.3 Breathing Field Lagrangian

We define the Lagrangian density:

$$\mathcal{L} = \frac{1}{2} \left( \partial_{\tau} \hat{\psi} \right)^{2} - \frac{1}{2} \left( \nabla_{\Omega} \hat{\psi} \right)^{2} - V(\hat{\psi})$$

Possible potentials include:

- $V = \frac{\lambda}{4}\hat{\psi}^4$  self-interacting breathing modes.
- $V = \alpha \sin^2(\hat{\psi}^2)$  Sionic stabilizing phase.
- $V = \xi R(x)\hat{\psi}^2$  curvature-coupled field.

# 13.4 Path Integral Formulation

The amplitude of breathing field transition becomes:

$$\mathcal{A} = \int \mathcal{D}\psi \, e^{i \int d\tau \, d\Omega \, \mathcal{L}}$$

This integral runs over all possible breathing histories  $\psi(\tau, x)$  along the membrane.

## 13.5 Particle Interpretations

- The vacuum is the Sionic mode:  $\psi_{\sigma}(\tau)$ .
- Interactions correspond to nonlinear breathing mode coupling.

# 13.6 Collapse and Measurement

- Collapse: contraction of  $\hat{\psi}$  into low-entropy phase attractors.
- Measurement: local  $\tau$ -gauge fixing.
- Entanglement: persistent  $\tau$ -correlated breathing across  $\Omega$ .

# 13.7 Cosmological Implications

- Vacuum energy: Breathing vacuum provides dynamic  $\rho_{vac}(\tau)$ .
- Inflation: Rapid breathing synchronization across  $\Omega$ .
- CMB structure: Frozen  $\tau$ -field correlations.

# 14 Foundational Axioms of BMQM: Quantum Breathing Space and Collapse

#### **Preliminaries**

Breathing Manifold  $\Omega$  A d-dimensional differentiable manifold equipped with a Riemannian metric  $g_{ij}$  and a globally defined curvature field R(x). Points on  $\Omega$  represent local membrane elements.

Internal Time  $\tau$  A monotonically oriented parameter that labels the intrinsic rhythmic evolution of  $\Omega$ .  $\tau$  is *not* an external coordinate but an internal phase coordinate.

**Breathing Field** A complex-valued function  $\psi: \Omega \times R_{\tau} \to C$  whose modulus and phase encode local amplitude and phase of membrane breathing.

## 14.1 Axiom I — Breathing Space Structure

The pair  $(\Omega, \tau)$  forms a fibre bundle  $\mathcal{B}$  in which the base space is  $\Omega$  and the fibre is the U(1) phase circle parameterised by  $\tau$ . Sections of  $\mathcal{B}$  correspond to permissible breathing fields  $\psi$ .

# 14.2 Axiom II — Breathing Dynamics

The unrestricted evolution of the breathing field is governed by the **Breathing Wave Equation** 

$$\partial_{\tau}^{2}\psi = \frac{2\psi(1-\psi^{2})}{(1+\psi^{2})^{3}} \ on \ (\Omega,\tau).$$
 (8)

Solutions are required to be  $C^{\infty}$  in both x and  $\tau$ .

#### 14.3 Axiom III — Quantum Promotion

Quantisation is achieved by promoting  $\psi$  to an operator-valued field  $\hat{\psi}$  satisfying the non-local commutation relation

$$[\hat{\psi}(x,\tau),\,\hat{\psi}^{\dagger}(x',\tau')] = i\,\Delta(x,x')\,\check{\delta}(\tau-\tau'),\tag{9}$$

where  $\Delta$  is a geometry–dependent kernel and  $\check{\delta}$  encodes rhythmic synchrony.

# 14.4 Axiom IV — Energy-Breathing Feedback

There exists a Hermitian operator  $\hat{H}[\hat{\psi}]$  (the breathing Hamiltonian) such that the generator of  $\tau$ -translations is given by

$$i\partial_{\tau}\hat{\psi} = [\hat{\psi}, \hat{H}]. \tag{10}$$

 $\hat{H}$  contains both gradient terms  $\nabla_{\Omega}\hat{\psi}$  and a potential  $V(\hat{\psi};R)$  coupling to membrane curvature.

# 14.5 Axiom V — Entropic Collapse Principle

Measurement corresponds to a completely positive, trace-preserving map  $\mathcal{M}$  acting on the breathing density operator  $\rho$  such that

$$S(\mathcal{M}(\rho)) \leq S(\rho),$$
 (11)

where  $S(\rho) = -\text{Tr}(\rho \log \rho)$  is the von Neumann entropy. Equality holds iff the measurement outcome is compatible with the pre–existing breathing configuration.

# 14.6 Axiom VI — Sionic Stability

The spectrum of  $\hat{H}$  admits a lowest non-zero frequency  $\omega_0$  whose square defines the Sionic constant  $\sigma = \omega_0^2$ . States evolving with fundamental frequency  $\omega_0$  are **Sionic modes** and act as global attractors under repeated entropic collapse.

#### 14.7 Axiom VII — Entanglement Cohesion

For any bipartition  $\Omega = \Omega_A \cup \Omega_B$ , the entanglement entropy

$$S_{\text{ent}} = -\text{Tr}_A(\rho_A \log \rho_A), \qquad \rho_A = \text{Tr}_B(\rho),$$
 (12)

is preserved under unitary  $\tau$ -evolution and can only decrease under local collapse maps acting on  $\Omega_A$  or  $\Omega_B$ . Non-vanishing  $S_{\rm ent}$  implies phase-locked breathing across the partition.

These axioms provide a minimal yet complete backbone for BMQM and its quantum field extension: they specify the geometric arena, dynamical law, quantisation rules, measurement/collapse mechanism, and the universal stabilising role of the Sionic mode.

This formulation transforms BMQM into a full field-theoretic framework, enabling the analysis of identity, collapse, entanglement, and vacuum structure as manifestations of quantum membrane field geometry.

# 15 Derived Theorems and Corollaries of BMQM

The following results are derived directly from the foundational axioms of BMQM and illustrate the logical structure and predictive power of the theory.

# 15.1 Theorem 1 (Sionic Quantization of Stable Periods)

**Statement:** Any breathing field  $\psi(\tau)$  satisfying the nonlinear breathing wave equation (Axiom II) and remaining periodic with minimal energy satisfies a quantized period:

$$T_{\sigma} = \frac{2\pi}{\sqrt{\sigma}}.$$

**Proof Sketch:** By Axiom VI, the lowest stable frequency is  $\omega_0 = \sqrt{\sigma}$ . Periodic solutions of the form  $\psi(\tau) = A\sin(\omega_0\tau + \phi)$  satisfy the equation in the low-amplitude limit. Thus, the base period of Sionic breathing is fixed by  $\sigma$ .

# 15.2 Corollary 1 (Sionic Time Unit)

**Statement:** The Sionic period defines a natural time unit:

$$[\tau] = T_{\sigma} = \frac{2\pi}{\sqrt{\sigma}}.$$

This is the intrinsic unit of temporal resolution in breathing-based evolution.

## 15.3 Theorem 2 (Entropy Monotonicity Under Measurement)

**Statement:** Let  $\mathcal{M}$  be a measurement map acting on the density operator  $\rho$  as defined in Axiom V. Then

$$S(\mathcal{M}(\rho)) \le S(\rho),$$

and equality holds if and only if the measurement is non-informative. **Proof Sketch:**  $\mathcal{M}$  is completely positive and trace-preserving. The monotonicity of von Neumann entropy under CPTP maps follows from Lindblad's inequality. The strict inequality for informative measurements follows from the contraction of support.

# 15.4 Corollary 2 (Collapse Fixes Breathing Gauge)

**Statement:** A measurement that yields a definite outcome collapses  $\psi$  into a single gauge frame in the U(1) fibre of breathing phases.

# 15.5 Theorem 3 (Entanglement as -Phase Correlation)

**Statement:** For a bipartite breathing state  $\Psi(x_1, x_2, \tau)$ , the entanglement entropy  $S_{\text{ent}} > 0$  if and only if  $\Psi$  cannot be factorized as  $\psi_1(x_1, \tau) \otimes \psi_2(x_2, \tau)$ .

**Proof Sketch:** Follows from standard properties of Schmidt decomposition and Axiom VII. Non-factorizability implies nontrivial eigenvalue spectrum of the reduced state  $\rho_1$ , hence positive entropy.

## 15.6 Corollary 3 (Persistence of Entanglement Through )

**Statement:** If  $\Psi$  evolves unitarily under Axiom IV, then  $S_{\text{ent}}(\tau)$  is conserved. Collapse or measurement on one side can only reduce it.

## 15.7 Theorem 4 (Breathing Vacuum Energy)

Statement: The energy density of the breathing vacuum is bounded below by:

$$\rho_{\rm vac} \ge \frac{1}{2} \sigma |\psi_{\sigma}|^2$$

**Interpretation:** Even the breathing ground state (Sionic mode) carries finite energy, forming a dynamic vacuum structure.

These theorems establish the predictive reach of the axioms and prepare the foundation for the physical, computational, and cosmological consequences of BMQM.

# 16 Canonical Examples and Solutions in BMQM

This section presents illustrative, solvable configurations of the BMQM framework. These examples demonstrate the mathematical behavior and physical interpretation of breathing fields under intrinsic time  $\tau$ .

# 16.1 Example 1: The Sionic Breathing Mode

The fundamental breathing pattern of the membrane is governed by the nonlinear differential equation:

$$\frac{d^2\psi}{d\tau^2} = \frac{2\psi(1-\psi^2)}{(1+\psi^2)^3}$$

This equation admits stable, periodic solutions under suitable initial conditions. For instance, with  $\psi(0) = 0.7$ ,  $\dot{\psi}(0) = 0$ , the solution  $\psi_{\sigma}(\tau)$  demonstrates a Sionic cycle of coherent oscillation:

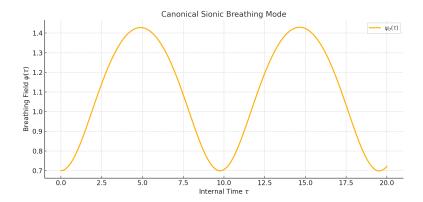

Figure 6: Canonical Sionic breathing mode  $\psi_{\sigma}(\tau)$ . This mode stabilizes with minimal entropy and defines the unit of internal time.

#### 16.2 Example 2: Entangled Phase-Locked Breathing

Consider two spatially separated membrane regions  $\Omega_1$  and  $\Omega_2$ , each supporting local breathing fields:

$$\psi_1(\tau) = \sin(\omega_{\sigma}\tau), \qquad \psi_2(\tau) = \sin(\omega_{\sigma}\tau + \frac{\pi}{2})$$

Their joint breathing state:

$$\Psi_{AB}(\tau) = \frac{1}{\sqrt{2}} (\psi_1 \otimes \psi_2 + \psi_2 \otimes \psi_1)$$

is maximally entangled. Despite spatial separation, the two fields maintain a fixed breathing phase relation, illustrating BMQM's geometric interpretation of nonlocal entanglement.

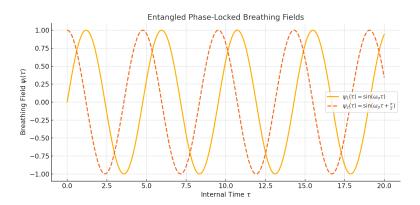

Figure 7: Two entangled breathing fields in phase-lock:  $\psi_1(\tau)$  and  $\psi_2(\tau)$ . Their synchronized evolution encodes shared identity across disjoint membrane regions.

These examples showcase the dynamical richness of BMQM: from isolated, entropy-minimizing stability to coherent entanglement through rhythmic -phase locking.

# 17 Diagrammatic Geometry of BMQM

The geometry of BMQM is encoded not only in differential structure, but also in phase bundles, entanglement loops, and collapse flows across the membrane  $\Omega$ . This section illustrates these relationships through idealized diagrams and topological constructs.

## 17.1 The Breathing Bundle

Each point  $x \in \Omega$  hosts a local fibre of internal time  $\tau$ , forming a **U(1)** phase bundle over the base membrane:

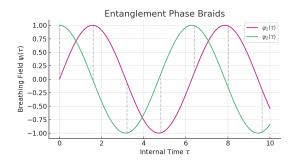

$$\mathcal{B} := (\Omega, U(1)_{\tau}, \pi)$$

This diagram represents:

- Base: spatial membrane  $\Omega$ , possibly curved.
- Fibres: circular internal phase orbits, one per point.
- Sections: breathing fields  $\psi(x,\tau)$  as smooth maps selecting a phase per location.

# 17.2 Entanglement as -Phase Braiding

Entangled regions are phase-locked across nonlocal separations. The -evolution of entangled regions traces a **braided pattern** in fibre phase space:

This phase braid encodes:

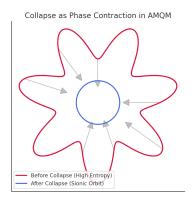

• Non-separability: trajectories of  $\psi_1$  and  $\psi_2$  intertwine.

• Persistent correlation:  $\tau$ -loops remain synchronized.

• Measurement effects: collapse collapses the braid into a trivial loop.

# 17.3 Collapse as Phase Contraction

Collapse corresponds to a **geometric contraction** of phase orbits into lower entropy attractors.

• Before collapse: the state traces a complex, high-entropy path over phase space.

• After collapse: the state locks into a coherent, low-dimensional orbit—usually the Sionic mode.

These diagrammatic structures support the deeper interpretation of BMQM as a field theory of geometry-infused identity, expressed not in positions but in synchronized, quantized rhythms.

# 18 Category-Theoretic Recasting of BMQM

The categorical formulation of BMQM provides a high-level abstraction of breathing dynamics, measurement, and identity. It organizes the theory into morphisms, functors, and transformations that mirror the internal structure of space, evolution, and collapse.

## 18.1 The Breathing Category $\mathcal{B}$

- Objects: Breathing configurations  $\chi_{\tau} = (\Omega, \psi(\tau), H(\tau))$  at internal time  $\tau$ .
- Morphisms: Time-evolution maps  $\Phi_{\tau_1}^{\tau_2}: \chi_{\tau_1} \to \chi_{\tau_2}$ , defined by solutions to the breathing wave equation.
- Composition:  $\Phi_{\tau_2}^{\tau_3} \circ \Phi_{\tau_1}^{\tau_2} = \Phi_{\tau_1}^{\tau_3}$ .
- Identity Morphism:  $id_{\tau}: \chi_{\tau} \to \chi_{\tau}$ .

#### 18.2 Functors as Observables

- A functor  $\mathcal{O}: \mathcal{B} \to \mathcal{G}$  maps breathing states to measurable geometric structures (e.g., energy, entropy, coherence).
- $\mathcal{O}(\chi_{\tau}) = S(\rho_{\tau}), E(H(\tau)), \nabla \psi.$
- Morphisms are mapped to evolution of observables:  $\mathcal{O}(\Phi_{\tau_1}^{\tau_2})$ .

# 18.3 Natural Transformations as Collapse

- Let  $\mathcal{O}, \mathcal{O}' \colon \mathcal{B} \to \mathcal{G}$  be two observables.
- A natural transformation  $\eta: \mathcal{O} \Rightarrow \mathcal{O}'$  represents the entropy-reducing process of measurement.
- Each object  $\chi_{\tau}$  has a morphism  $\eta_{\chi_{\tau}} : \mathcal{O}(\chi_{\tau}) \to \mathcal{O}'(\chi_{\tau})$ .

# 18.4 Higher Structures and Identity

- 2-morphisms encode changes in observational perspective or gauge (meta-evolution).
- Limits of diagrams  $\lim_{i} \mathcal{O}_{i}(\chi)$  define stable identity or breathing coherence classes.
- Collapse is a limit-preserving transformation  $\eta: \mathcal{O} \Rightarrow \mathcal{O}'$  that selects minimal entropy within an equivalence class.

## 18.5 Breathing as a Functorial Dynamics

The entire BMQM framework becomes a functor:

$$BMQM: \mathcal{T}_{\tau} \longrightarrow \mathcal{S}_{\Omega}$$

where:

- $\mathcal{T}_{\tau}$  is the category of internal time phases,
- $S_{\Omega}$  is the category of membrane states,
- and morphisms are breathing transformations.

# 19 The Total Action of BMQM

The total action principle in BMQM provides a unifying variational framework from which the fundamental dynamics of breathing, entropy, identity, and collapse emerge. It encodes kinetic motion in internal time  $\tau$ , spatial coherence over the membrane  $\Omega$ , curvature interaction, and entropy as a driving field.

#### 19.1 Action Definition

We define the total action  $S[\psi, H]$  as:

$$S[\psi, H] = \int d\tau \, d^n x \left[ \frac{1}{2} \left( \frac{d\psi}{d\tau} \right)^2 - \frac{1}{2} |\nabla \psi|^2 - V(\psi, R) + \alpha \log S[\rho(\psi)] \right]$$

## 19.2 Term Interpretations

- Kinetic Term:  $\frac{1}{2}(d\psi/d\tau)^2$  captures breathing motion across  $\tau$ , the internal time parameter.
- Spatial Gradient:  $-\frac{1}{2}|\nabla\psi|^2$  suppresses sharp spatial fluctuations, enforcing smoothness on the membrane  $\Omega$ .
- Potential Term:  $V(\psi, R)$  governs nonlinear breathing dynamics and allows coupling to membrane curvature R(x). Example potentials include:
  - $V = \frac{\lambda}{4}\psi^4$  for nonlinear stability,
  - $-V = \alpha \sin^2(\psi^2)$  for Sionic locking,
  - $-V = \xi R(x)\psi^2$  for curvature response.
- Entropy Term:  $\alpha \log S[\rho(\psi)]$  introduces thermodynamic feedback. As entropy drops, this term minimizes the action, leading to collapse into ordered states.

## 19.3 Physical Interpretation

This action unifies:

- Geometry and identity via  $\psi(\tau, x)$ ,
- Dynamics and evolution through the Euler-Lagrange equation,
- Collapse and measurement as entropy-reducing variational paths,
- Thermodynamics and structure in the breathing field's entropy coupling.

The BMQM action thus governs not just what evolves, but how breathing collapses into identity — where structure, phase, and entropy resonate into rhythm.

This recasting elevates BMQM to a universal, abstract framework capable of encoding internal dynamics, phase coherence, and collapse through categorical semantics.

# 20 Qiskit Encoding of BMQM Breathing Simulation

```

for i in range(2**num_qubits):
  shifted = (i + 1) % (2**num_qubits)
   U_matrix[shifted, i] = np.exp(1j * np.pi / 8) # phase-shifted circular shift
U_op = Operator(U_matrix)
qc.unitary(U_op, \Omega, label="\diamondsuit \diamondsuit \bigstar \Omega")
# Simulate and print final statevector
backend = Aer.get_backend('statevector_simulator')
result = backend.run(assemble(transpile(qc, backend))).result()
final_state = result.get_statevector()
for i, amp in enumerate(final_state):
  print(f''|\{i:03b\}>: amplitude = \{amp:.4f\}'')
```

#### This Qiskit code:

- Discretizes the membrane  $\Omega$  into 8 qubit sites.
- Initializes a breathing pattern  $\psi(\tau, x)$  via a sine-modulated amplitude register.
- Evolves the system with a convolution-like operator simulating  $\mathcal{H} \star \Omega$ .

# 21 Final Conclusion and Outlook

In this work, we introduced Breathing Membrane Quantum Mechanics (BMQM) as a geometric, thermodynamic, and algebraic generalization of standard quantum theory. At its heart lies the rhythmic evolution of a membrane  $\Omega$  governed by an internal breathing time  $\tau$ , with quantum states defined as breathing amplitudes  $\psi(\tau, x)$ .

Central to the formulation is the breathing Hamiltonian  $H \star \Omega$ , a convolutional structure that encodes energy feedback from membrane geometry. This operator governs both local and global evolution, integrating curvature, entanglement, and information flow into a single dynamical law.

Another foundational element is the *Sionic constant*  $\sigma=1.7365$ , emerging from the nonlinear stability equation as a universal breathing invariant. It defines the baseline frequency of coherent identity and provides a bridge between dynamics and thermodynamics. In high-symmetry limits,  $\sigma=1.7365$  governs entropy reduction during measurement and coherence preservation under entanglement.

Through perturbative and categorical reformulations, we showed that standard quantum mechanics emerges from BMQM in the linear limit. Yet BMQM goes beyond: it captures identity as coherent phase structure, entanglement as synchronized -dynamics, and collapse as localized pinching in breathing amplitude space.

Future directions include deeper algebraic classifications, physical simulations on quantum hardware, and experimental detection of -phase coherence. BMQM invites us to think of reality not as static particles in space, but as a living, breathing membrane — where memory is rhythm, identity is structure, and the universe evolves not through time, but through breath.
